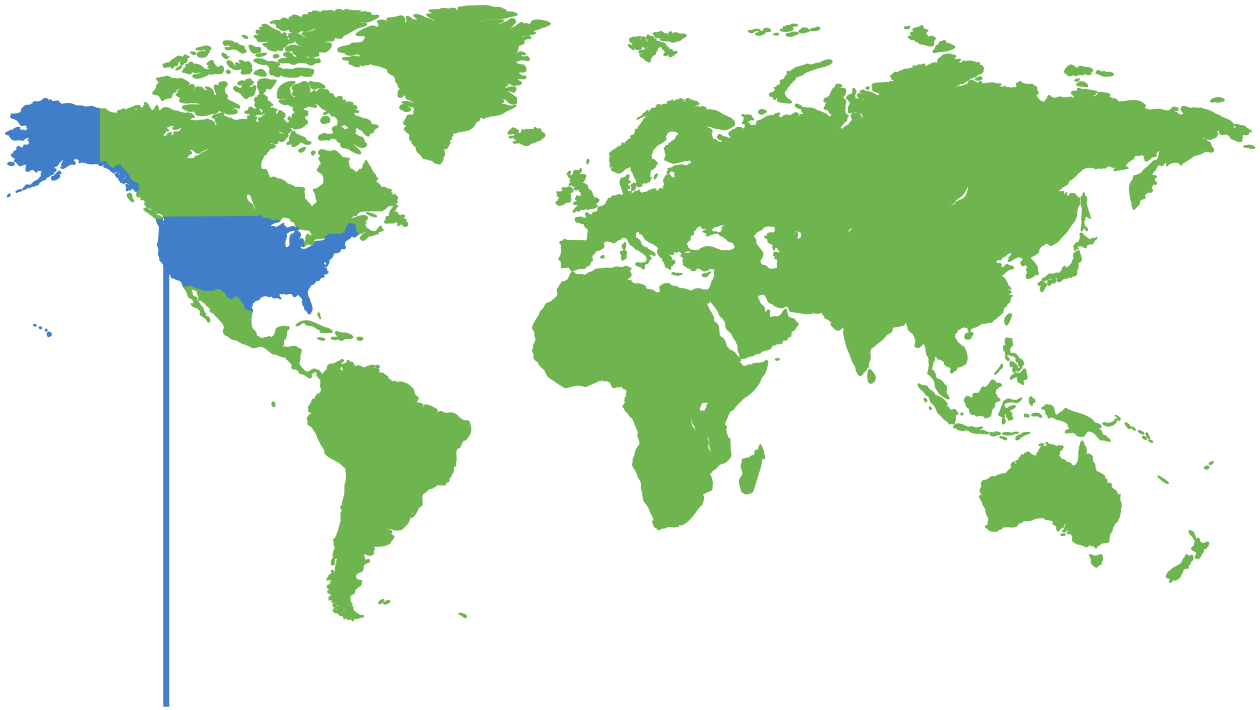
Wet AMD: Leading Cause of Blindness in Patients Over 65

20M people living with wet AMD worldwide[1,2]



1.5M people impacted by wet AMD in the U.S.[1,2]

Opportunity for New Wet AMD Treatment

Current Standard of Care Drives Suboptimal Outcomes	Gene Therapy: Overcomes Wet AMD Treatment Burden
Frequent bolus anti-VEGF IVT injections required leading to poor compliance[3,4]	Single, easily administered in-office IVT treatment
Lifetime need for frequent injections overburdens patients, caregivers, and healthcare providers	Durable, disease modifying therapy, potentially “one and done” functional cure
$139 billion in U.S. annual economic burden of vision loss, including falls, cognitive decline and depression[5]	Readily deployable in the U.S. and around the world addressing direct and indirect costs

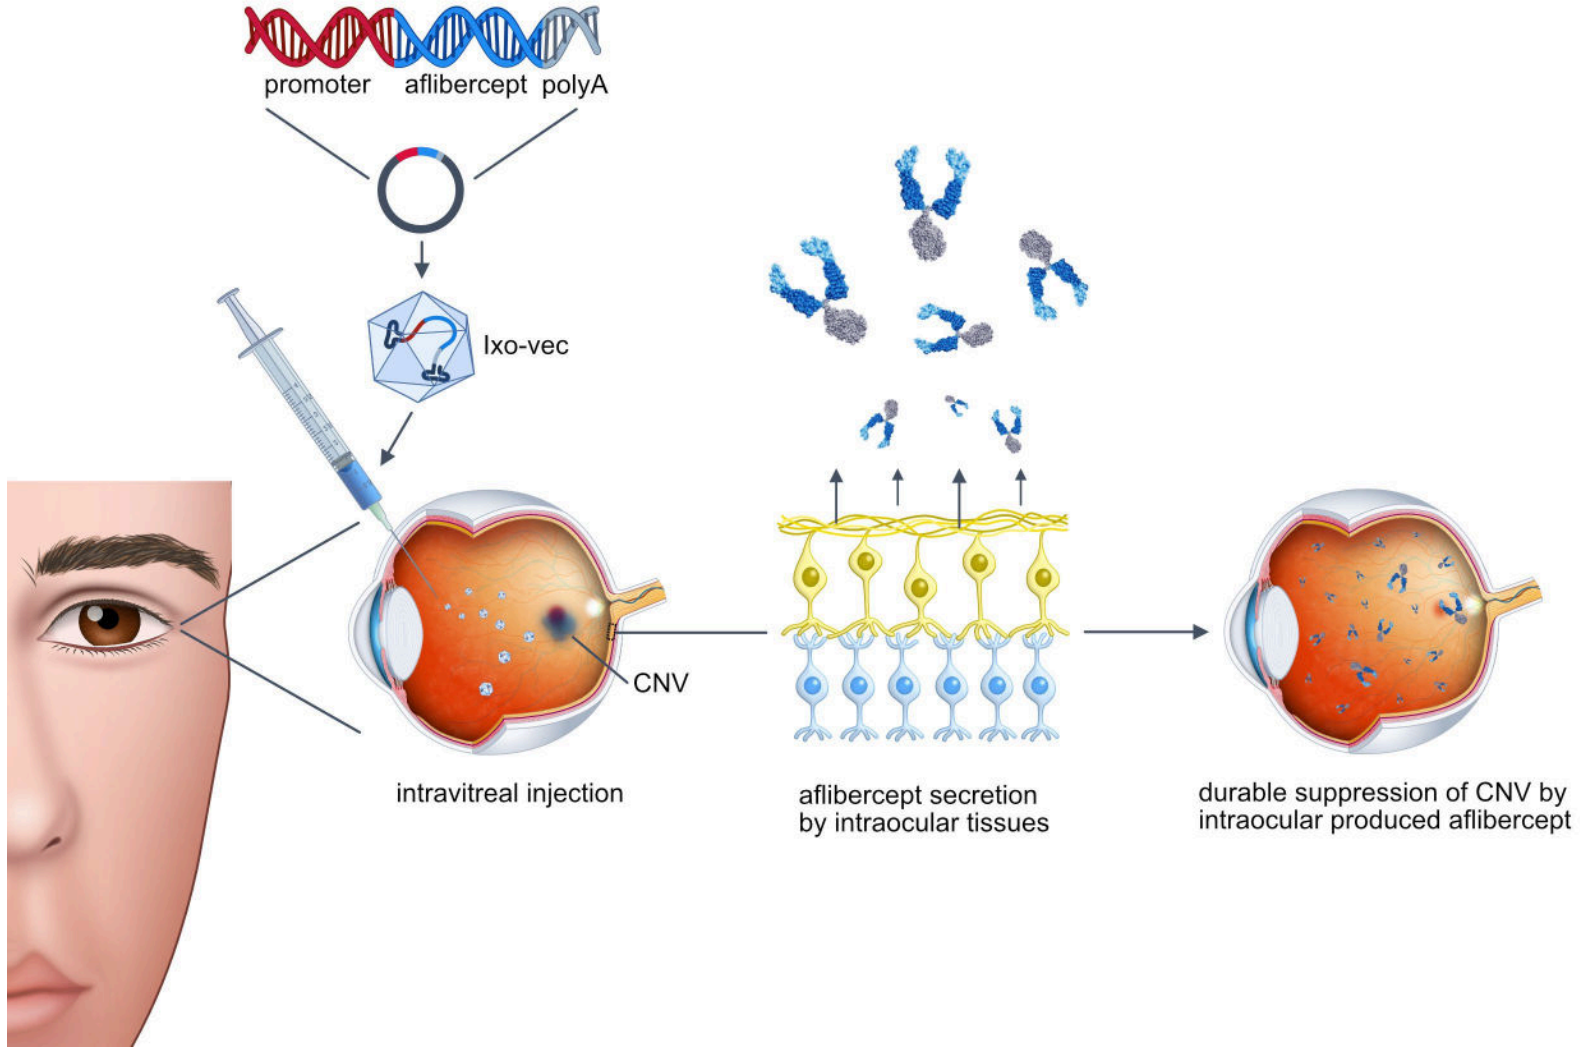
ADVERUM

Ixo-vec is a gene therapy biofactory approach designed for continuous delivery of aflibercept (anti-VEGF) by single intravitreal injection



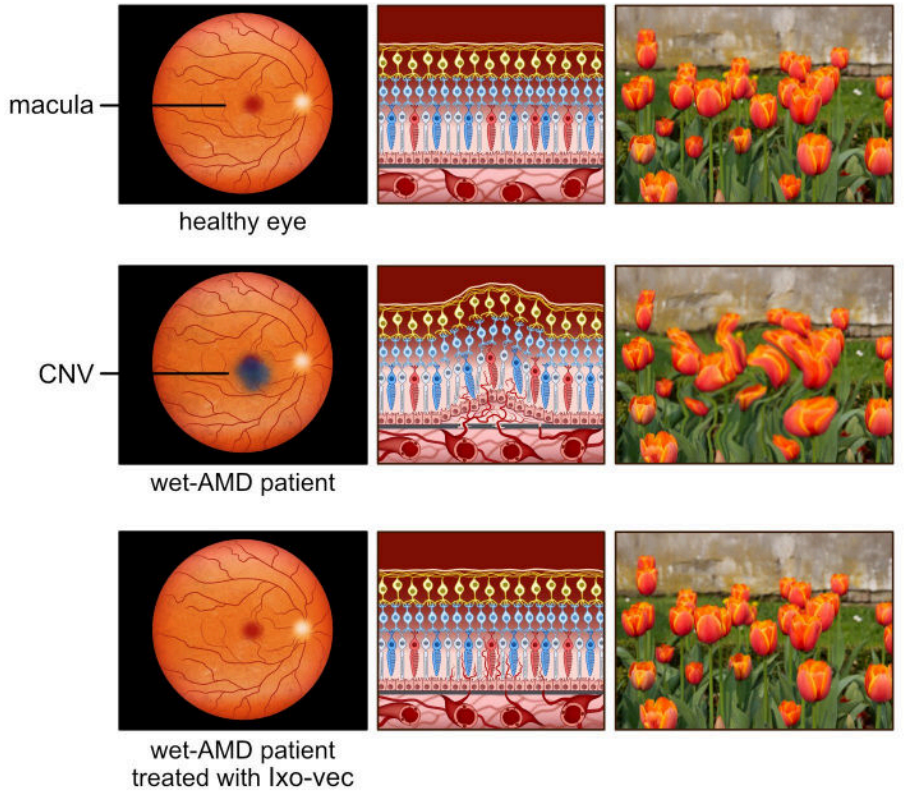


Illustration: Gardenia Gonzalez Gil

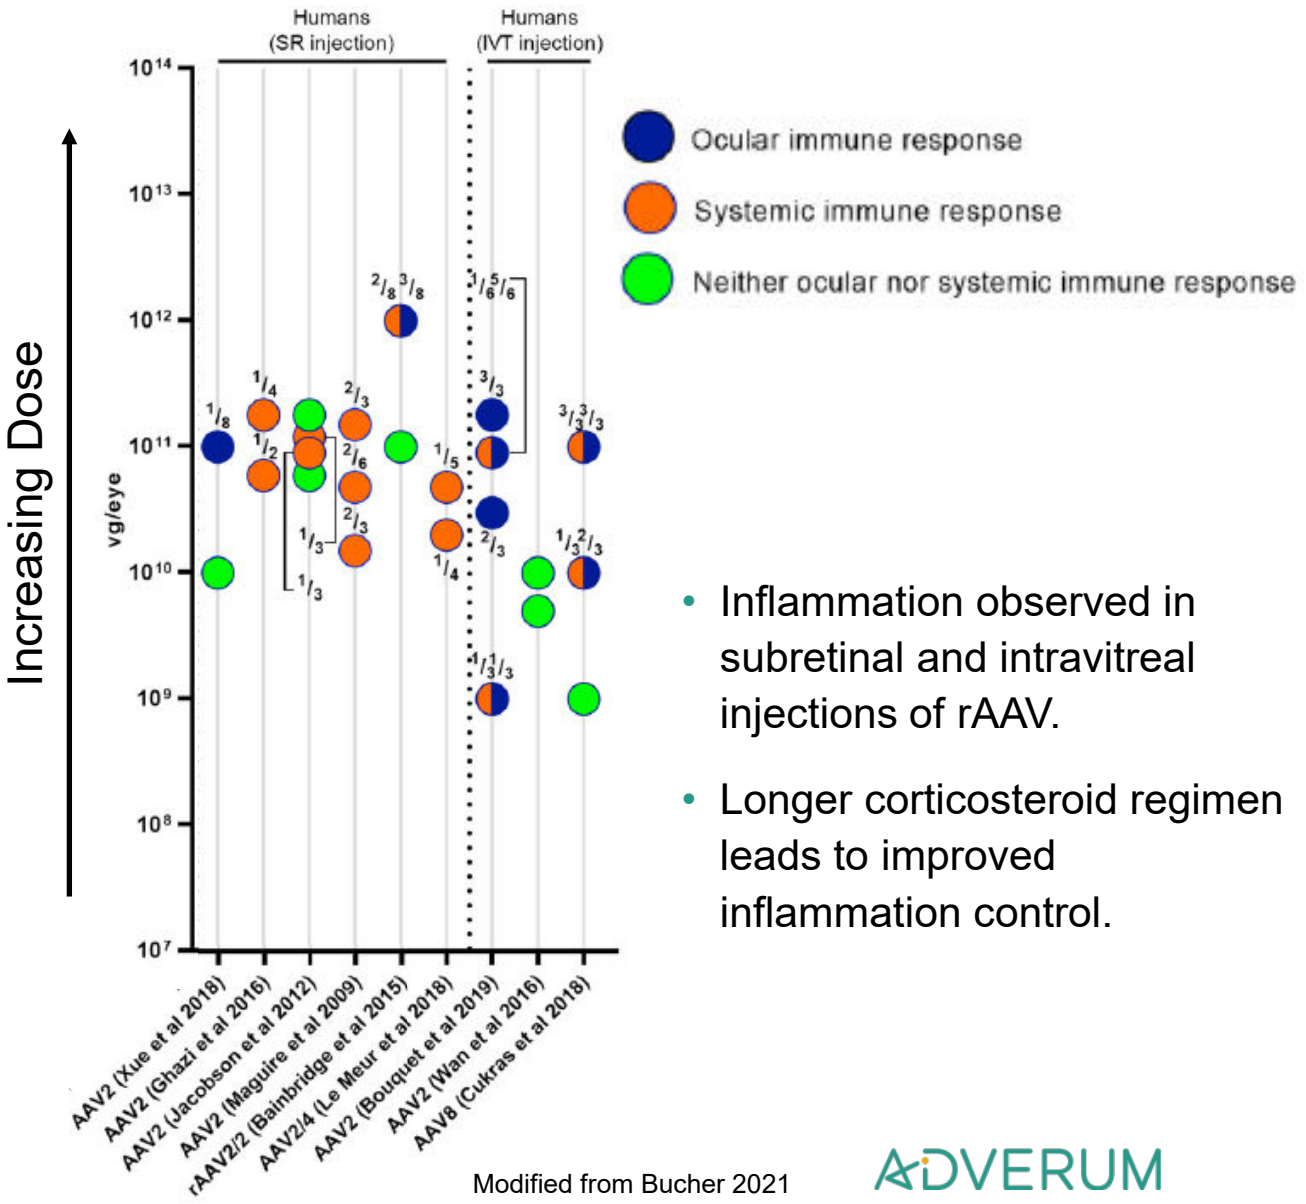
ADVERUM

Clinical implementation of gene therapy products is influenced by rAAV immune mediated inflammatory response

- Dose-dependent inflammation is observed across the gene therapy field, irrespective of route of administration and therapeutic modality.
- rAAV immunogenicity can be mitigated by dose reduction and improved corticosteroid regimen.
- Systems-wide analyses of nonclinical models could help identify molecular signatures reflective of the dose-dependent inflammation commonly associated with gene therapy.



- Inflammation observed in subretinal and intravitreal injections of rAAV.
- Longer corticosteroid regimen leads to improved inflammation control.

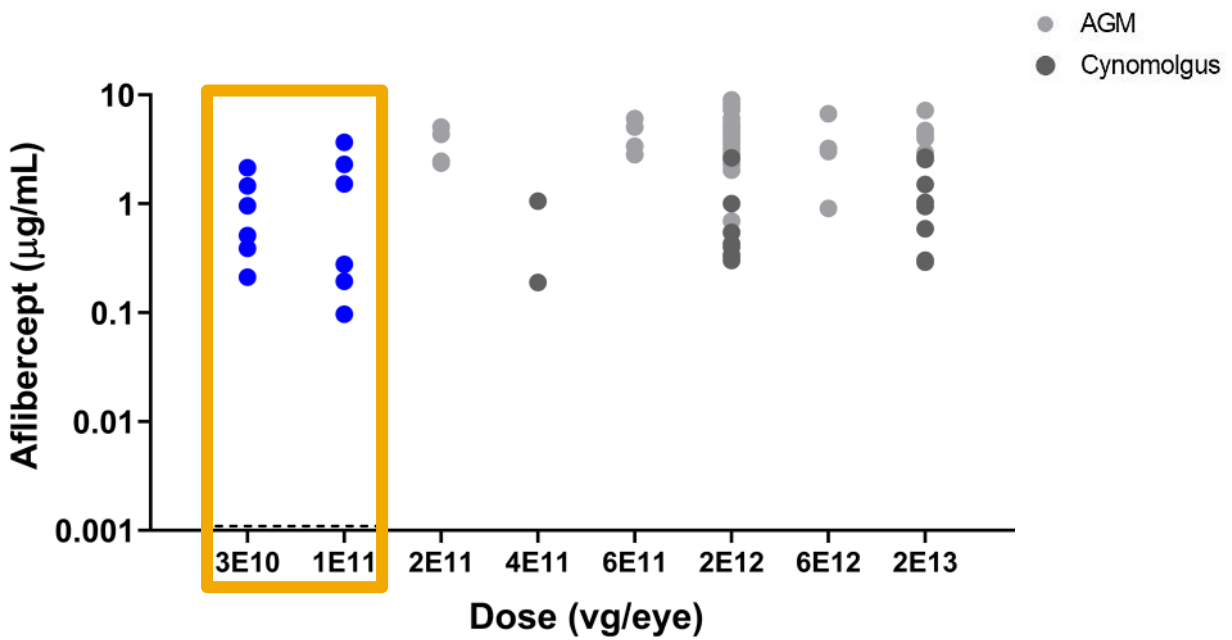
Modified from Bucher 2021

ADVERUM

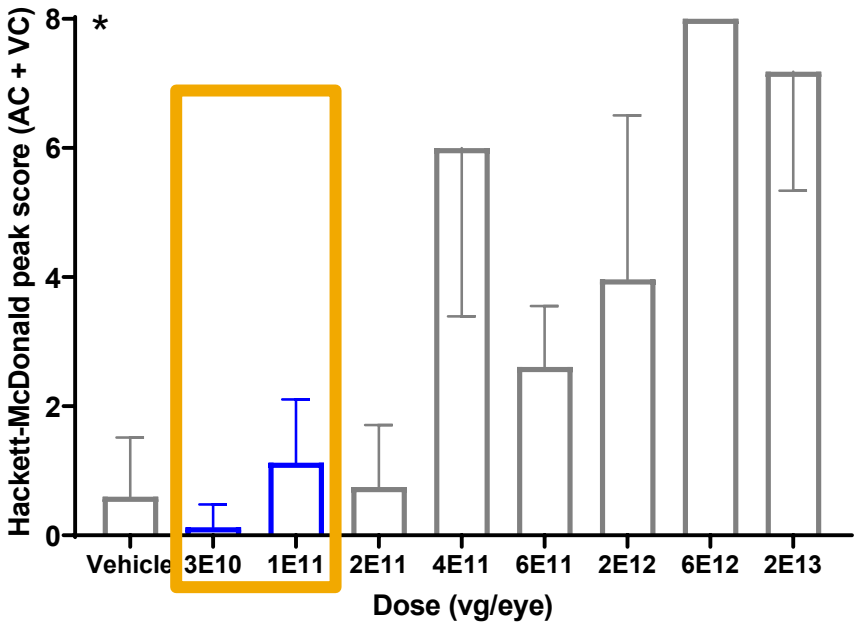
Ixo-vec potency enables ability to dose down to improve inflammation profile

Non-dose proportional aflibercept levels enable dose reduction to improve Ixo-vec inflammation profile while maintaining efficacy.

Vitreous Humor



Inflammation Scores



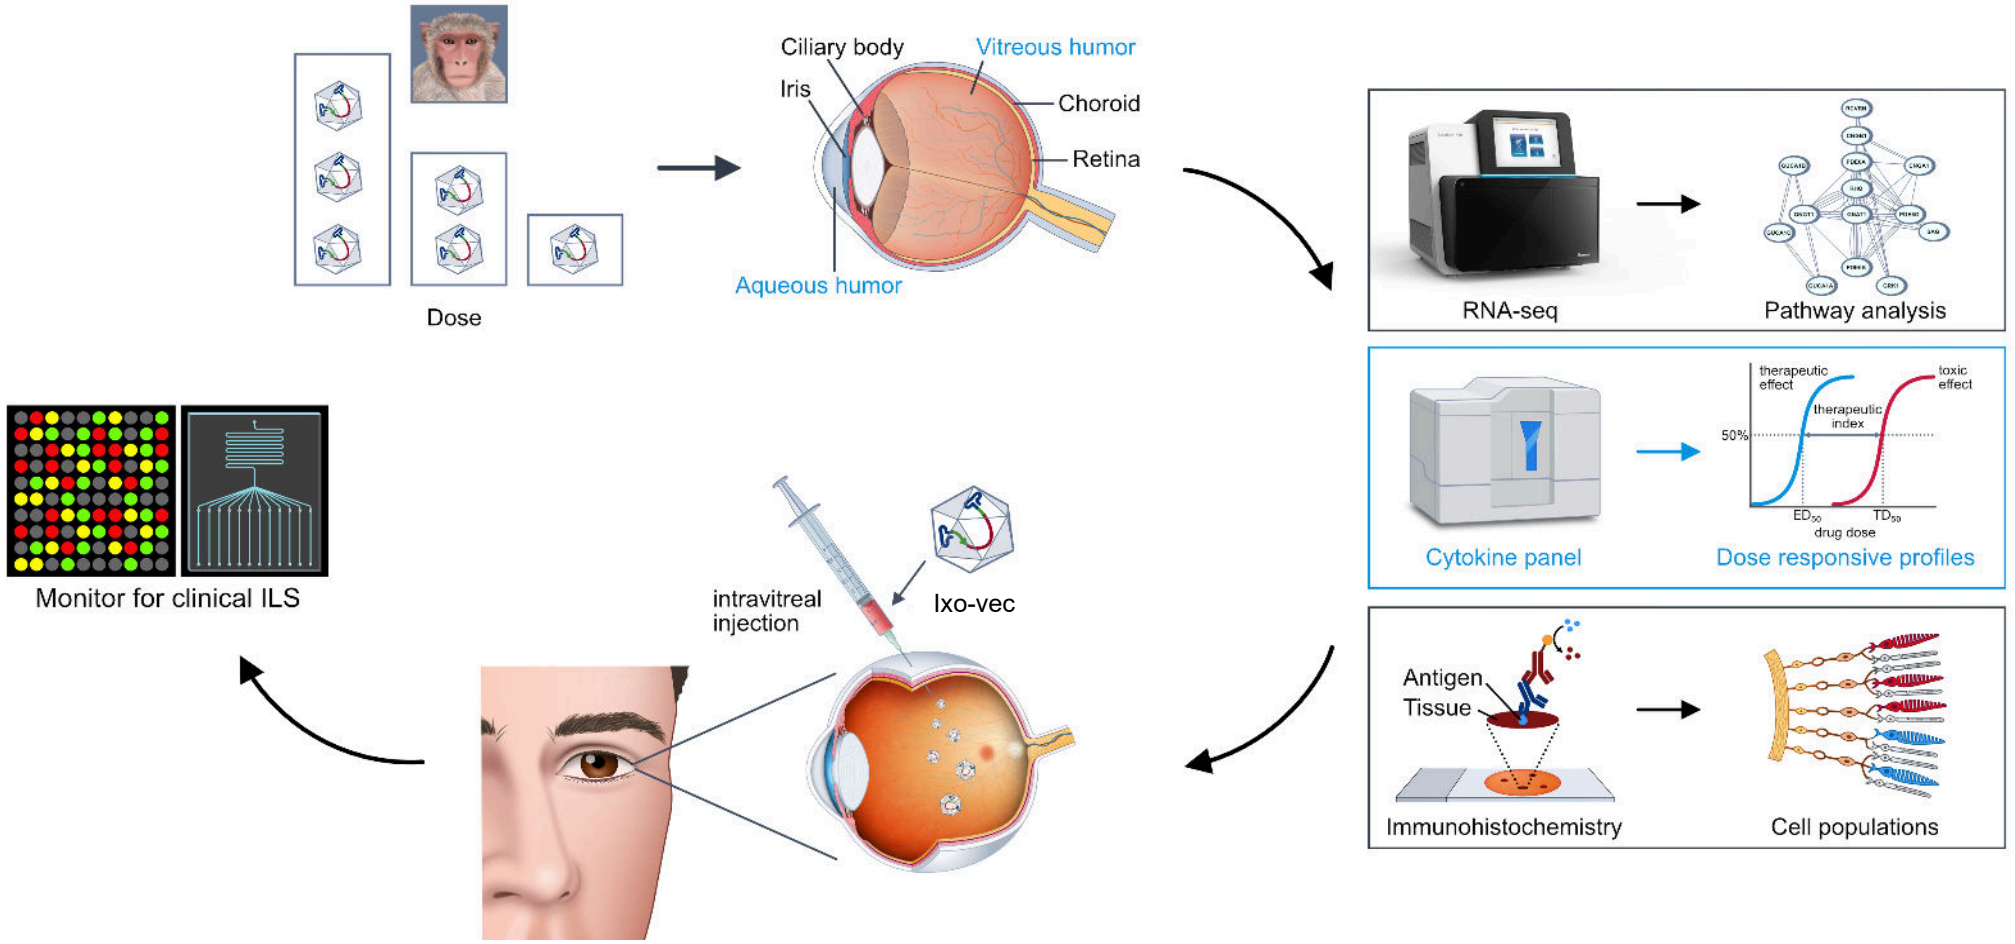
- NOAEL established at NHP dose of 1E11 vg/eye = 2E11 vg/eye human equivalent dose (HED).
- NHP dose of 3E10 vg/eye = 6E10 vg/eye HED.
- NHP dose of 1E11 vg/eye = 2E11 vg/eye HED.
- Doses in current LUNA clinical study outlined in orange boxes.

*Scale is cumulative of two parameters for maximum score of 8.

Schaefer-Swale K. Non-Clinical Data Support Efficacy and Tolerability of a Human Equivalent Dose of 6E10 vg/eye of ADVM-022 for the Treatment of Neovascular Age-Related Macular Degeneration. Poster presented at: ASGCT; May 16-19, 2022; Washington DC.

ADVERUM

Defining immune landscape signatures of Ixo-vec at supra-clinical doses



- Doses spanning 3-log fold range above NOAEL (1E11 vg/eye):
  - 4E11 vg/eye (low), 2E12 vg/eye (mid), 2E13 vg/eye (high)
- Single eye injected for each animal.
- Endpoint: 3 months post-dose.

- Multiple regions of retinal anatomy submitted for bulk RNA-seq.
- Pathway analysis was performed on RNA-seq samples.
- Parallel effort characterized inflammation by histology.

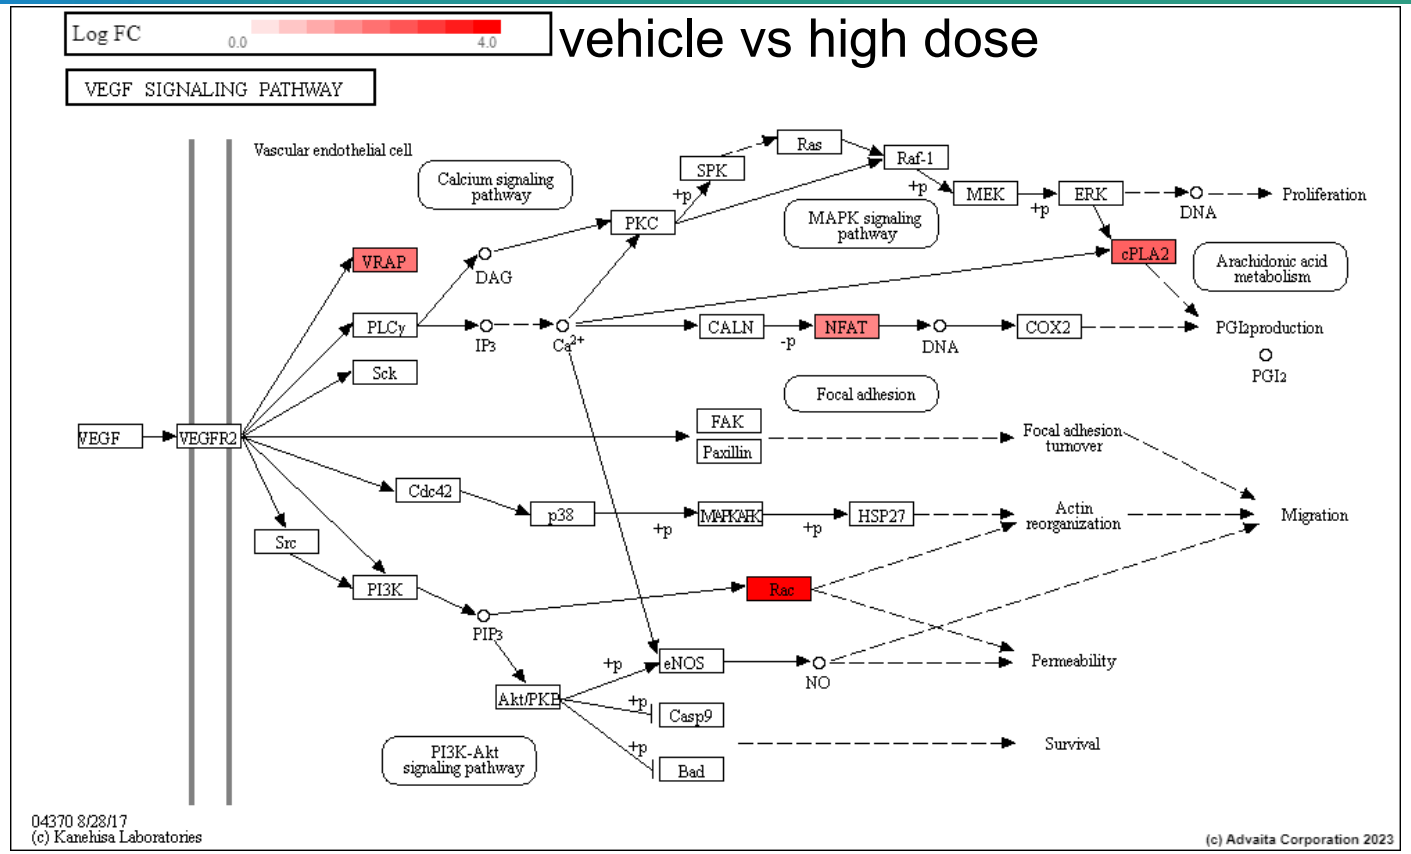
Illustration: Gardenia Gonzalez Gil

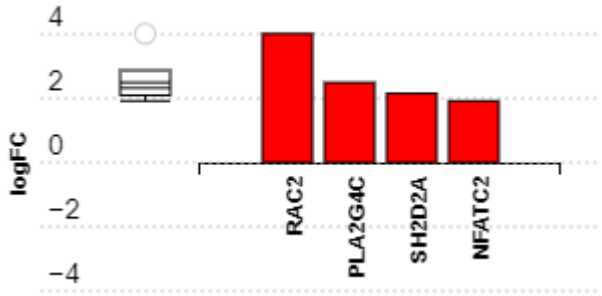
ADVERUM

Converging dataset strongly supports dose-dependent inflammatory response

- Pathway analysis was performed using multiple methods (topology and non-topology based).
  - Modulation is determined by the number of differentially expressed genes within a set as well as their position and magnitude of role within a pathway.
- Transcriptomic analysis did not support unfolded protein response (UPR), oxidative or endoplasmic reticulum (ER) stress, neovascularization, nor ciliary body dysfunction.
- Ixo-vec expression detected only in the dosed eye.
- Robust and dose-dependent activation of immune responses, consistent in nature across ocular tissues.
  - Severity in line with anticipated vector biodistribution.
- No evidence that ciliary body architecture was directly affected by Ixo-vec.
  - Only indirectly as dose-dependent inflammation increases.
  - Histology showed no disruption of ciliary body fold formation at any dose.
- RNA-seq and histopathology indicate activation of innate and adaptive immune systems consistent with dose-dependent rAAV-associated inflammation.

VEGF signaling is not activated in ocular tissues

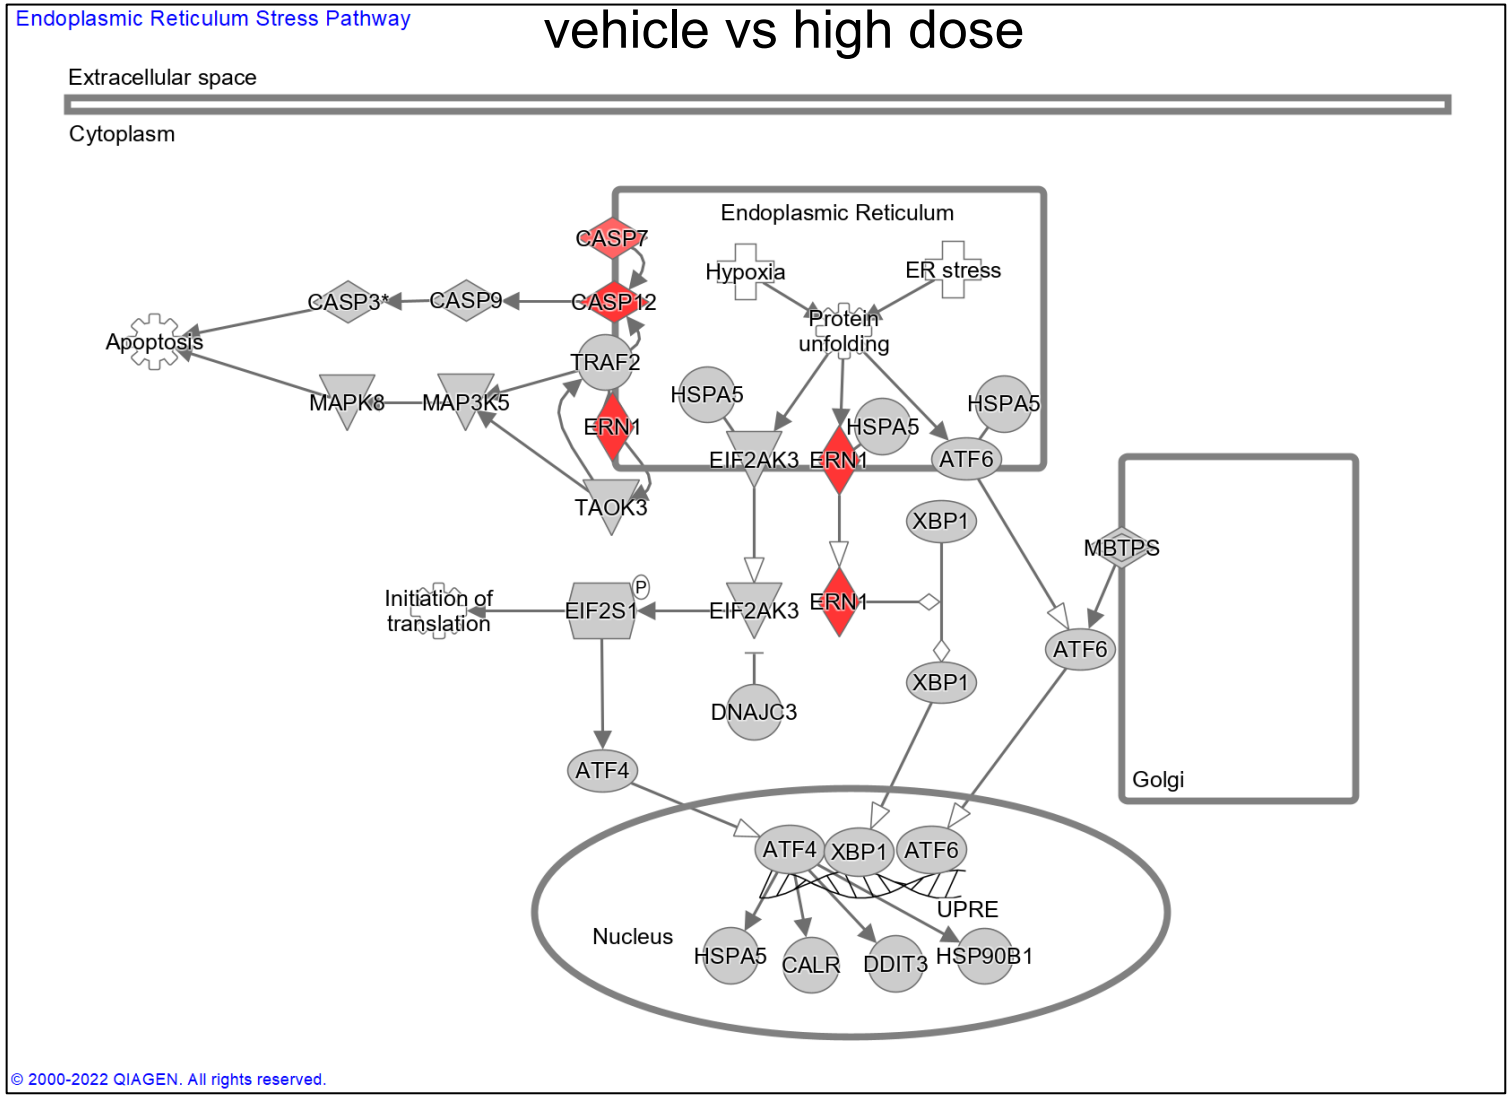




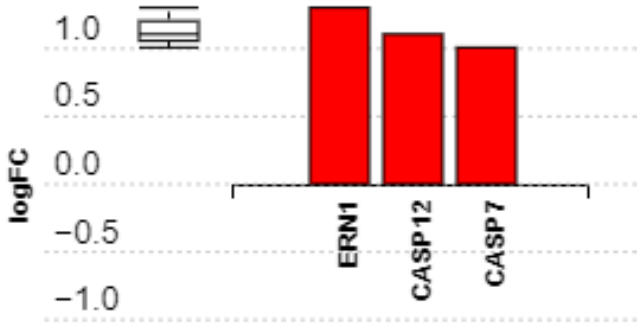
- Observation was similar across doses for all ocular tissues examined.
- Ixo-vec unlikely to exacerbate VEGF-mediated pathology of wet AMD.

ADVERUM

No evidence of UPR or ER stress by Ixo-vec dosing



- Cellular toxicity has been attributed to inefficiencies in transgene translation, folding, and post-transcriptional modification.[1, 2]
  - Ixo-vec expression unlikely induces cellular stress.
- UPR reportedly upregulated by rAAV transduction.[3, 4]
  - Transduction-mediated UPR unlikely to be observed at study endpoint.



- mRNA expression level exhibited little dose-dependence in ocular tissues. No alternative splicing observed.

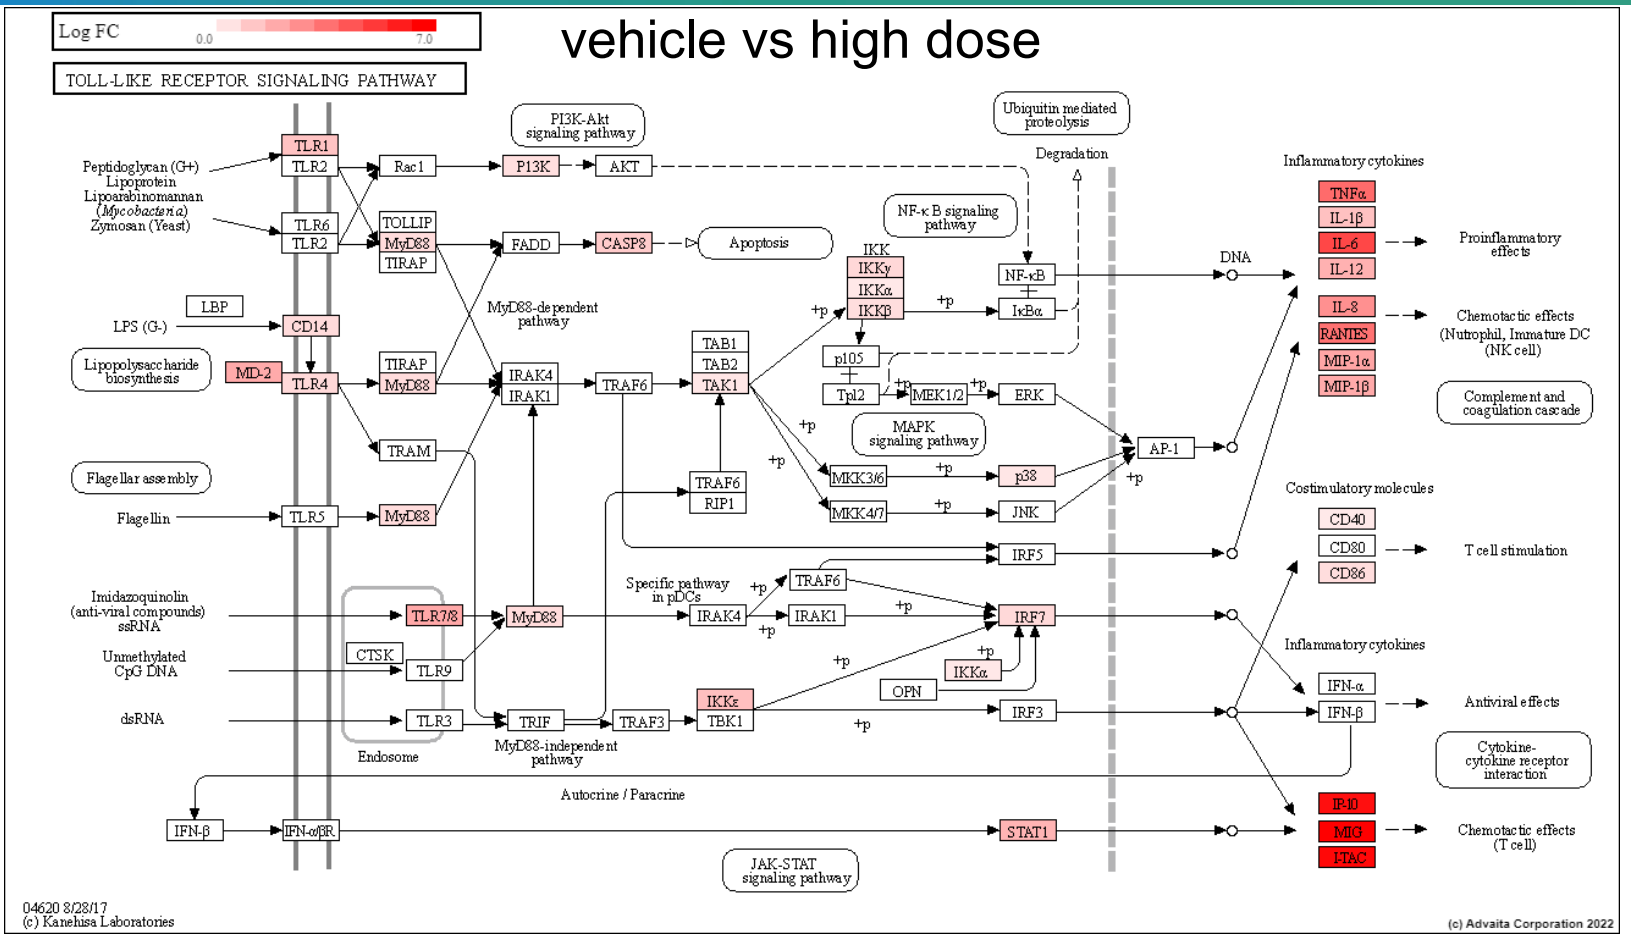
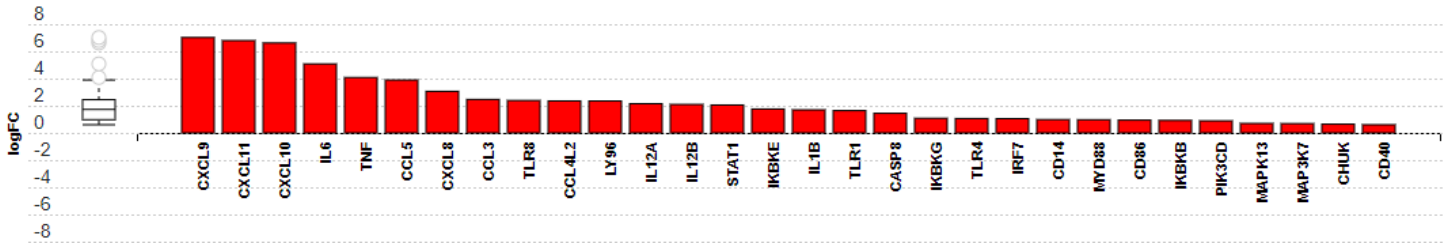
ADVERUM

Toll-like receptor signaling





- Unmethylated CpG DNA – TLR9 – MYD88 axis not activated.
- TLR8 suggests response to exogenous mRNA load.[1]
- TLR1/2/4 have reported activation by viral proteins.[2, 3]

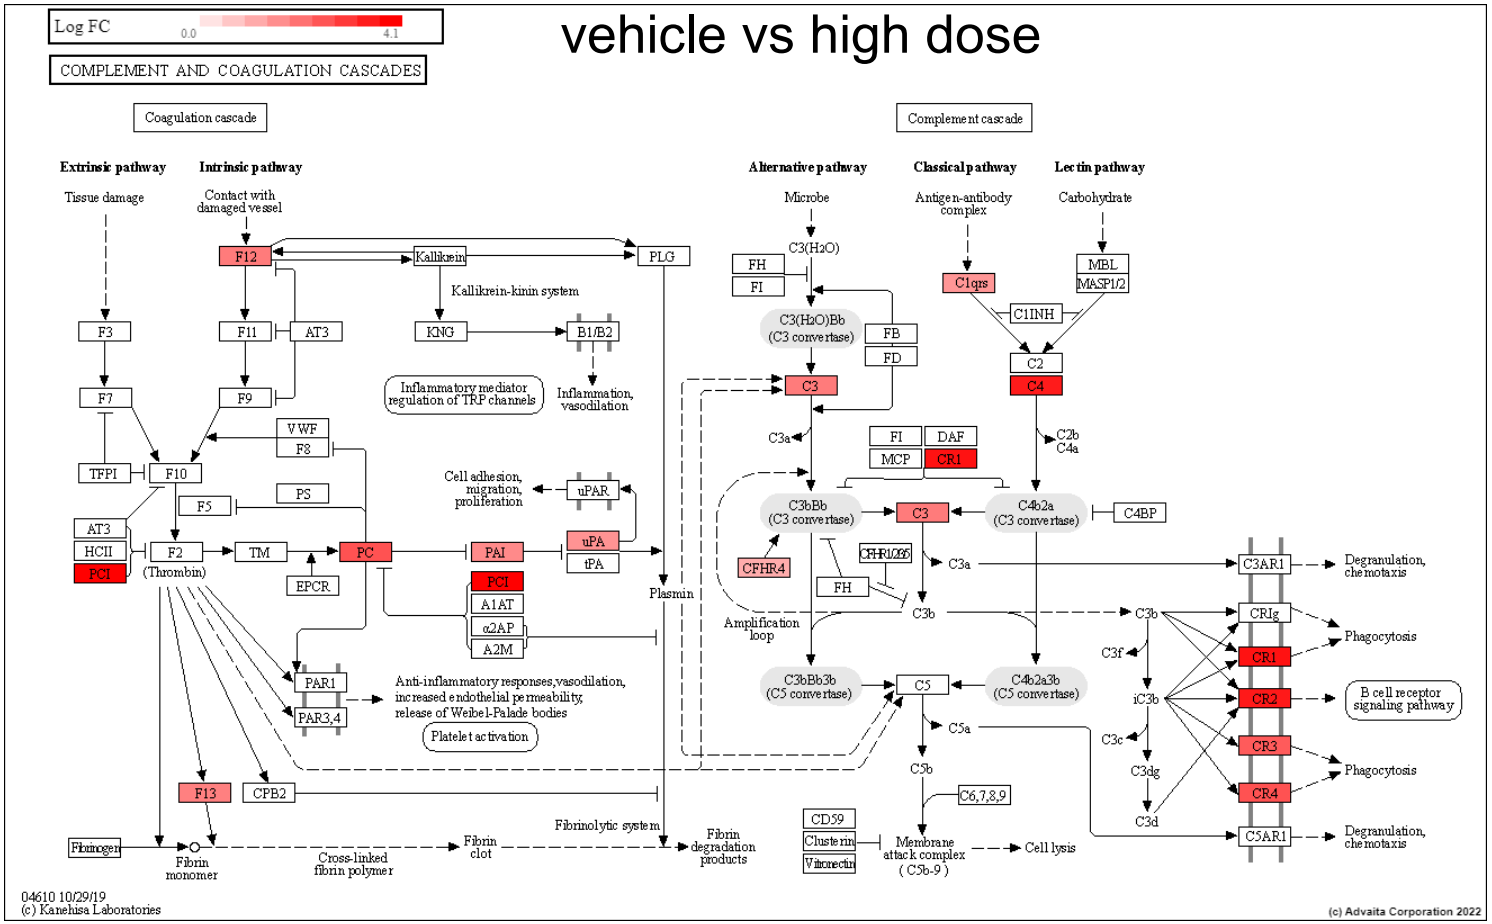
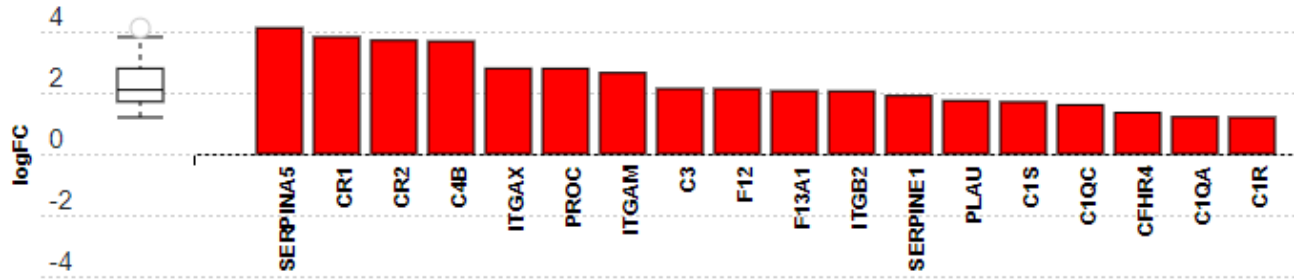
ADVERUM

Complement-mediated response observed in dose-responsive manner

vehicle vs high dose





- Could represent antibody complexes bound to rAAV capsid/protein.
- Complement activation previously reported as inflammatory response to high systemic dose of rAAV in clinical trials.[1, 2]
- Complement activation has been known to activate B cells.

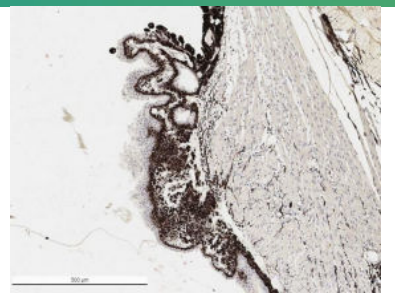
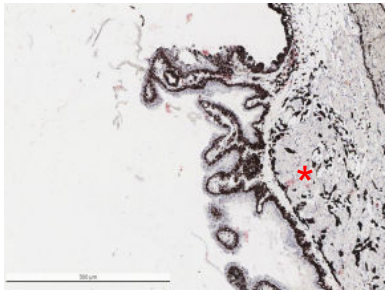
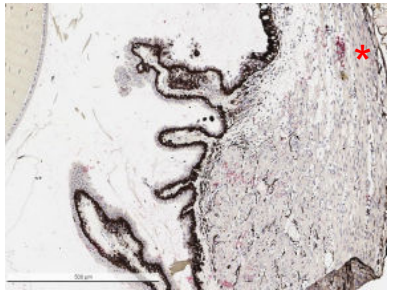
CD20+



Vehicle



Low dose



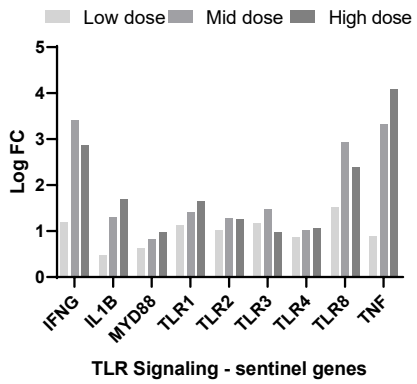
Mid dose

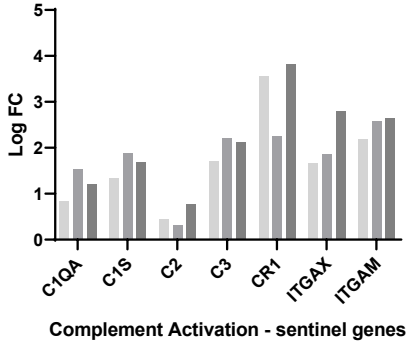
High dose

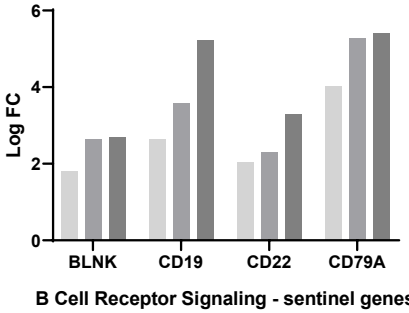
ADVERUM

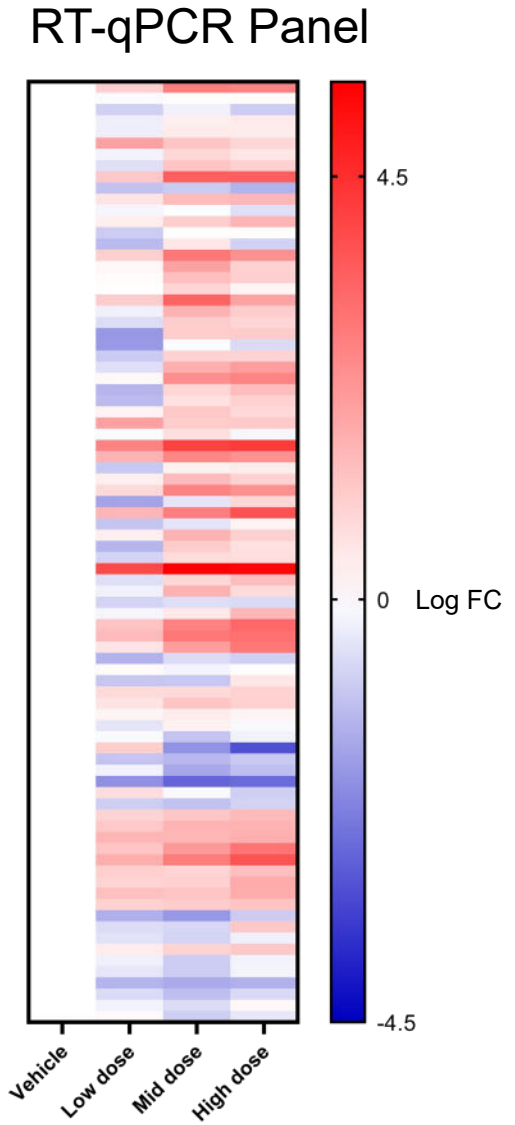
Creation of immune landscape signatures

- Sentinel genes were chosen to represent pathways identified by RNA-seq analysis.
- Concordance found between RNA-seq and RT-qPCR.
- Immune landscape signature (ILS) panel could enable:
  - Nonclinical evaluation to interrogate balance between efficacy/tolerability axis
  - Predict patient outcomes
  - Identify high risk patients (e.g., with microvascular comorbidities)
  - Stratify patients that may not need corticosteroids from those that are more susceptible to rAAV-immunogenicity and require them









ADVERUM

Conclusions

Pathway analysis and IHC converged on dose-dependent activation of innate and adaptive immune response pathways, consistent with rAAV-associated inflammation.

- Aflibercept expression levels plateaued across doses, unlike dose-dependent adaptive immune response.

- Immune landscape signatures of supra-clinical doses are consistent in nature across ocular tissues – predominately in the anterior tissues of the eye and retina.
  - Assessed 3-log fold range above NOAEL.
- No evidence that harnessing ocular cells as biofactories to produce aflibercept leads to expression-associated toxicity/inflammation.
- No evidence that ciliary body architecture was directly affected by Ixo-vec – only indirectly and at supra-clinical doses secondary to dose-dependent increase in inflammation.
- Use of lower doses and an improved steroid prophylaxis, implemented in the LUNA trial, are expected to improve Ixo-vec inflammation profile while preserving therapeutic levels of aflibercept.

Forward-Looking Statements

Statements contained in this document regarding matters, events, statistics, or clinical or financial results that may occur in the future are “forward-looking statements” within the meaning of the Private Securities Litigation Reform Act of 1995. Such statements include, but are not limited to, statements regarding plans and milestones related to Adverum’s product candidates, process development and manufacturing, clinical studies and trials, and regulatory filings, the therapeutic and commercial potential of Adverum’s product candidates and the sufficiency of Adverum’s resources to fund lead programs, all of which are based on certain assumptions made by Adverum on current conditions, expected future developments and other factors Adverum believes are appropriate under the circumstances. Adverum may not consummate any of these plans or these product, clinical development, process development, manufacturing, or regulatory goals in a timely manner, or at all, or otherwise carry out the intentions or meet the expectations or projections disclosed in its forward-looking statements, and you should not place undue reliance on these forward-looking statements. Actual results could differ materially from those anticipated in such forward-looking statements as a result of various risks and uncertainties, including risks inherent to, without limitation: Adverum’s novel technology, which makes it difficult to predict the timing of commencement and completion of clinical trials; regulatory uncertainties; enrollment uncertainties; the results of early clinical trials not always being predictive of future clinical trials and results; and the potential for future complications or side effects in connection with use of Ixo-vec. Additional risks and uncertainties facing Adverum are set forth under the caption “Risk Factors” and elsewhere in Adverum’s Securities and Exchange Commission (SEC) filings and reports, including Adverum’s Annual Report on Form 10-K for the year ended December 31, 2022 filed with the SEC on March 30, 2023. All forward-looking statements contained in this press release speak only as of the date on which they were made. Adverum undertakes no obligation to update such statements to reflect events that occur or circumstances that exist after the date on which they were made.

This document contains estimates, projections and other information concerning Adverum’s industry, business and the markets for certain drugs, including data regarding the estimated size of those markets, their projected growth rates and the incidence of certain medical conditions. Information that is based on estimates, forecasts, projections or similar methodologies is inherently subject to uncertainties and actual events or circumstances may differ materially from events and circumstances reflected in this information.
